EXPERIMENT NO: 2

BRIEF THEORY: Karnaugh maps are the most extensively used tool for simplification of Boolean functions. It is mostly used for functions having up to six variables beyond which it becomes very cumbersome. In an n-variable K-map there are $2^n$ cells. Each cell corresponds to one of the combination of n variable, since there are $2^n$ combinations of n-variables. Gray code has been used for the identification of cells.

Example- $f(A, B, C, D) = A'B'C + AB'C + ABC' + ABC$ (SOP)

Reduced form is $BC + AC + AB$ and POS form is $f(X, Y, Z) = Y' (X'+Y+Z') (X+Z)$

LOGIC DIAGRAM

EXPERIMENT NO: 3

Aim: Verification of State Tables of Rs, J-k, T and D Flip-Flops using NAND & NOR Gates

APPARATUS REQUIRED: IC’ S 7400, 7402 Digital Trainer & Connecting leads.

BRIEF THEORY:

- **RS FLIP-FLOP**: There are two inputs to the flip-flop defined as R and S. When I/Ps R = 0 and S = 0 then O/P remains unchanged. When I/Ps R = 0 and S = 1 the flip-flop is switches to the stable state where O/P is 1 i.e. SET. The I/P condition is R = 1 and S = 0 the flip-flop is switched to the stable state where O/P is 0 i.e. RESET. The I/P condition is R = 1 and S = 1 the flip-flop is switched to the stable state where O/P is forbidden.

- **JK FLIP-FLOP**: For purpose of counting, the JK flip-flop is the ideal element to use. The variable J and K are called control I/Ps because they determine what the flip-flop does when a positive edge arrives. When J and K are both 0s, both AND gates are disabled and Q retains its last value.

- **D FLIP –FLOP**: This kind of flip flop prevents the value of D from reaching the Q output until clock pulses occur. When the clock is low, both AND gates are disabled D can change value without affecting the value of Q. On the other hand, when the clock is high, both AND gates are enabled. In this case, Q is forced to equal the value of D. When the clock again goes low, Q retains or stores the last value of D. a D flip flop is a bistable circuit whose D input is transferred to the output after a clock pulse is received.

- **T FLIP-FLOP**: The T or "toggle" flip-flop changes its output on each clock edge, giving an output which is half the frequency of the signal to the T input. It is useful for constructing binary counters, frequency dividers, and general binary addition devices. It can be made from a J-K flip-flop by tying both of its inputs high.

EXPERIMENT NO: 4

Aim:- Implementation and Verification of Decoder/De-Multiplexer and Encoder using Logic Gates.

APPARATUS REQUIRED: IC 7447, 7-segment display, IC 74139 and connecting leads.

BRIEF THEORY:

**ENCODER:** An encoder is a device, circuit, transducer, software program, algorithm or person that converts information from one format or code to another, for the purposes of standardization, speed, secrecy, security, or saving space by shrinking size. An encoder has M input and N output lines. Out of M input lines only one is activated at a time and produces equivalent code on output N lines. If a device output code has fewer bits than the input code has, the device is usually called an encoder. For example Octal-to-Binary Encoder take 8 inputs and provides 3 outputs, thus doing the opposite of what the 3-to-8 decoder does. At any one time, only one input line has a value of 1. The figure below shows the truth table of an Octal-to-binary encoder.

For an 8-to-3 binary encoder with inputs I0-I7 the logic expressions of the outputs Y0-Y2 are:

\[
Y_0 = I_1 + I_3 + I_5 + I_7 \\
Y_1 = I_2 + I_3 + I_6 + I_7 \\
Y_2 = I_4 + I_5 + I_6 + I_7
\]

**DECODER:** A decoder is a device which does the reverse operation of an encoder, undoing the encoding so that the original information can be retrieved. The same method used to encode is usually just reversed in order to decode. It is a combinational circuit that converts binary information from n input lines to a maximum of \(2^n\) unique output lines. In digital electronics, a decoder can take the form of a multiple-input, multiple-output logic circuit that converts coded inputs into coded outputs, where the input and output codes are different. e.g. n-to-\(2^n\), binary-coded decimal decoders. Enable inputs must be on for the decoder to function, otherwise its outputs assume a single "disabled" output code word. In case of decoding all combinations of three bits eight (\(2^3 = 8\)) decoding gates are required. This type of decoder is called 3-8 decoder because 3 inputs and 8 outputs. For any input combination decoder outputs are 1.

**DEMULTIPLEXER:** Demultiplexer means generally one into many. A demultiplexer is a logic circuit with one input and many outputs. By applying control signals, we can steer the input signal to one of the output lines. The ckt. has one input signal, m control
signal and n output signals. Where $2^n = m$. It functions as an electronic switch to route an incoming data signal to one of several outputs.

Quiz Questions with answer.

Q. 1 What do you understand by decoder?
Ans. A decoder is a combinational circuit that converts binary information from \( n \) input lines to a maximum of \( 2^n \) unique output lines. Most IC decoders include one or more enable inputs to control the circuit operation.

Q. 2 What is demultiplexer?
Ans. The demultiplexer is the inverse of the multiplexer, in that it takes a single data input and \( n \) address inputs. It has \( 2^n \) outputs. The address input determine which data is selected.
output is going to have the same value as the data input. The other data outputs will have the value 0.

Q. 3 What do you understand by encoder?
Ans. An encoder or multiplexer is therefore a digital IC that outputs a digital code based on which of its several digital inputs is enabled.

Q. 4 What is the main difference between decoder and demultiplexer?
Ans. In decoder we have n input lines as in demultiplexer we have n select lines.

Q. 5 Why Binary is different from Gray code?
Ans. Gray code has a unique property that any two adjacent gray codes differ by only a single bit.

Q. 6 Write down the method of Binary to Gray conversion. Ans. Using the Ex-Or gates.

Q. 7 Convert 0101 to Decimal.
Ans. 5

Q. 8 Write the full form of ASCII Codes?

Q. 9. If a register containing 0.110011 is logically added to register containing 0.101010 what would be the result?
Ans. 111011

Q. 10. Binary code is a weighted code or not? Ans. Yes

EXPERIMENT NO: 9

**Aim:** To Design & Verify Operation of Half Adder & Full Adder.

**APPARATUS REQUIRED:** Power supply, IC’s, Digital Trainer, Connecting leads.

**BRIEF THEORY:** We are familiar with ALU, which performs all arithmetic and logic operation but ALU doesn’t perform/process decimal no’s. They process binary no’s.

**Half Adder:** It is a logic circuit that adds two bits. It produces the O/P, sum & carry. The Boolean equation for sum & carry are:

\[
\text{SUM} = A + B \\
\text{CARRY} = A \cdot B
\]

Therefore, sum produces 1 when A & B are different and carry is 1 when A & B are 1. Application of Half adder is limited.

**Full Adder:** It is a logic circuit that can add three bits. It produces two O/P sum & carry. The Boolean Equation for sum & carry are:

\[
\text{SUM} = A + B + C \\
\text{CARRY} = A \cdot B + (A + B) \cdot C
\]

Therefore, sum produces one when I/P is containing odd no’s of one & carry is one when there are two or more one in I/P.

**LOGIC DIAGRAM:**
